Our repository has the structure:

```
mini-project3/
├── concurrency/
│   ├── airport-troubles/
│   └── birthday-boy/
├── xv6/
│   ├── user/
│   ├── kernel/
│   ├── Makefile
│   └── ...
├── ai-usage.md
└── README.md
```

The makefiles for airport-troubles and birthday-boy arent given, we have to write them ourselves
The boilerplates for xv6 portion is provided to you. Don't make changes to these portions unless absolutely necessary. We are supposed to make changes to the xv6 portion.
Make sure not only to fulfill every requirement, but keep a detailed log of the sequence in which you made every implementation, how you fulfilled a requirement, what changes you made in what file. I need to remake the project you create on my own, making periodic git commits, therefore I require full knowledge of what is being added, why, in what order, and how to test working of code at that stages. Design choices and assumptions must be explicitly stated.

Only commits to the main branch of the repo shall be counted. If branching has been done, it is forbidden to squash merge, rebase or delete the branch after merging.

Code must be modular. The inputs must strictly be in the formatt that is mentioned, as our code shall be run through autograder.

Make sure to follow the instructions in the screenshots precisely
